What does this project do?

field-desk: a CRM for a distribution business, extended with two accounting corrections

In one paragraph

field-desk is a web application that a distribution company uses to run its customer-facing workflow: Sales punches orders, a key-account manager (KAM) approves them, the Warehouse loads, dispatches and confirms deliveries and records returns, and Accounts records customer payments, credit notes and reward points. Every money-affecting step goes through one strict, audited "action" pipeline, so customer balances always add up.

The people (roles) who use it

Role	What they do
Sales	Create customers, punch and edit orders, cancel unshipped quantity
KAM	Approve or reject orders; authorise corrections
Warehouse	Start loading, dispatch, confirm delivery, record returns
Accounts	Receive payments, allocate cash, issue and apply credit notes, redeem points
Admin	Can do everything

The money model in plain words

- **Charge:** when goods are delivered, the customer owes money for those goods (one goods charge per delivery confirmation).
- **Receipt:** cash the customer paid. Cash is applied to the oldest outstanding charges first. Cash not yet applied is "free cash".
- **Credit note:** a part of a receipt reserved as credit, which can be applied to a charge or refunded.
- **Reward points:** earned when goods are paid for in cash; locked while unpaid; clawed back if the payment is reversed after the points were spent.
- **Append-only history:** nothing is edited or deleted. A mistake is fixed by adding a compensating (opposite) entry.

What I added (the take-home task)

The assignment ("Business Rules Engine") asked for two real features while keeping the code from turning into a tangle of special cases.

Ticket	Problem	What the system now does
FDSK-169	Accounts recorded a payment against the wrong customer.	Command **MOVE_PAYMENT**: the receipt is marked reversed, an identical receipt is created on the right customer, and both customers' charges, cash and points are recalculated.

Ticket	Problem	What the system now does
FDSK-170	A KAM marked 10 units delivered but only 6 arrived.	Command **CORRECT_DELIVERY**: delivery is lowered to 6 using reversal rows, the charge shrinks, extra cash is released, points are re-locked. When the other 4 are confirmed later, everything re-applies automatically.

Technology

- Monorepo with pnpm workspaces: **client** (React + Vite), **server** (NestJS + Drizzle ORM + SQLite), **shared** (Zod contracts used by both).
- Tests with the Node test runner against a real SQLite database through HTTP.
- Private repo Aman-0402/field-desk, imported from AviKKi/field-desk with its original history kept.
